solidification processes | Britannica

Vacuum Arc Remelting (VAR) is typically the final melting process in the production of a wide range of alloys including superalloys, titanium, zirconium and specialty steels. During this process, a DC arc is struck under vacuum between a consumable electrode and a water-cooled copper crucible.

Vacuum Arc - an overview | ScienceDirect Topics

Vacuum arc remelting further removes lingering inclusions to provide superior steel cleanliness and remove gases like oxygen, nitrogen and hydrogen. Controlling the rate at which these droplets form and solidify ensures a consistency of chemistry and microstructure throughout the entire VIM-VAR ingot, making the steel more resistant to fracture or fatigue.

eminent institutes of the USSR. The Paton Institute, internationally famous for its entrepreneurial efforts in electrical welding processes, is also famous for its application of electrically based processes in melting and remelting of high alloy and high-temperature materials. These include the ESR (electroslag re melting) process, the ESC (electroslag casting) process, skull remelting based on electron-beam processes, plasma arc processes, and electric arc processes. Along with the ESR process for ingot production is the commercial plasma arc remelt process

for specialty steels, particularly where high nitrogen contents may be desired, as in austenitic stainless steels. Major industrial centers are now scattered throughout the USSR and are a major factor in high-alloy, high strength, low- and high-temperature materials. The ESR process was developed in response to the Western development of the VAR (vacuum arc remelting) process for producing very highly alloyed materials during the growth period of the jet engine age. The VAR and ESR processes utilize different purification and refinement processes that

are extremely critical in very highly, complexly alloyed superalloys and high-speed tool steels. In water-cooled remelt systems, they also achieve relatively rapid (directional) solidification, minimizing segregation and coarse phase separation of undesirable impurity elements or elements that tend to form coarse brittle phases.

Two applications of vacuum technology to metallurgy are discussed. One concerns the consumable-electrode vacuum-arc remelting of AISI 316 stainless steel. An air-

Download Ebook Vacuum Arc Remelting Of Steel And Alloys Technological

melted and a vacuum-arc remelted heat are compared with respect to composition, processing and welding, room- and high-temperature mechanical properties, magnetic permeability, inclusion count, and behavior in the Huey corrosion test. The vacuum heat was lower in carbon, oxygen, and hydrogen than the air-melted heat. The low oxygen and hydrogen were attributed to the melting process, while the low carbon was not. Both heats were similar in processing and welding behavior as well as in mechanical and physical properties. In Huey corrosion tests of

Download Ebook Vacuum Arc Remelting Of Steel And Alloys

sensitized material, the air-melted steel was attacked much faster than the vacuum-melted material. However, this difference was ascribed to the difference in carbon content between the two steels. Thus, in this study, no differences attributable to the consumable-electrode vacuum-arc remelting process were observed.

Accurate control of the electrode gap in a vacuum arc remelting (VAR) furnace has been a goal of melters for many years. The size of the electrode gap has a direct influence on ingot

Download Ebook Vacuum Arc Remelting Of Steel And Alloys Technological

solidification structure. At the high melting currents (30 to 40 kA) typically used for VAR of segregation insensitive Ti and Zr alloys, process voltage is used as an indicator of electrode gap, whereas drip-short frequency (or period) is usually used at the lower currents (5 to 8 kA) employed during VAR of superalloys. Modern controllers adjust electrode position or drive velocity to maintain a voltage or drip-short frequency (or period) set-point. Because these responses are non-linear functions of electrode gap and melting current, these controllers

Download Ebook Vacuum Arc Remelting Of Steel And Alloys Technological

have a limited range for which the feedback gains are valid. Models are available that relate process voltage and drip-short frequency to electrode gap. These relationships may be used to linearize the controller feedback signal. An estimate of electrode gap may then be obtained by forming a weighted sum of the independent gap estimates obtained from the voltage and drip-short signals. By using multiple independent measures to estimate the gap, a controller that is less susceptible to process disturbances can be developed. Such a controller was designed, built and

Aircraft and aerospace industries for materials possessing high strength and high toughness. By varying the composition and heat treatment, the 9Ni-4Co-xC steels can develop strengths in the 200 to 300 ksi tensile-strength range and reportedly possess high toughness. The lower carbon grades have excellent weldability, developing strength in the 180 to 200 ksi range with high toughness without the need for preheat or postweld-heat treatment. (Author).
